### ABSTRACT

In this paper we introduce a new class of sets called #regular generalized closed (briefly, #rg-closed) sets in topological space. We prove that this class lies between closed sets and rg-closed sets. We discuss some basic properties of #regular generalized closed sets. Applying this we introduce a new space called  $T_{\#rg}$  space.

**Keywords:** rw-open sets, #rg-closed sets,  $T_{\#rg}$ -space.

**2000 Mathematics Subject Classification:** 54A05

---

### INTRODUCTION:

Regular open sets and strong regular open sets have been introduced and investigated by Stone [17] and Tong [18] respectively. Levine [8,9], Biswas [3], Cameron [4], Sundaram and Sheik John [16], Bhattacharyya and Lahiri [2], Nagaveni [12], Pushpalatha [15], Gnanambal [6], Gnanambal and Balachandran [7], Palaniappan and Rao [13], Maki, Devi and Balachandran [7], and Benchalli and Wali [1] introduced and investigated semi open sets, generalized closed sets, regular semi open sets, weakly closed sets, semi generalized closed sets, weakly generalized closed sets, strongly generalized closed sets, generalized pre-regular closed sets, regular generalized closed sets, generalized  $\alpha$ -generalized closed sets and  $R_w$ -closed sets respectively. We introduce a new class of sets called #regular generalized closed sets which is properly placed in between the class of closed sets and the class of rg-closed sets.

Throughout this paper  $(X, \tau)$  represents a topological space on which no separation axiom is assumed unless otherwise mentioned. For a subset  $A$  of a topological space  $X$ ,  $cl(A)$  and  $int(A)$  denote the closure of  $A$  and the interior of  $A$  respectively.  $X \setminus A$  denotes the complement of  $A$  in  $X$ . We recall the following definitions and results.

**Definition: 1.1** A subset  $A$  of a space  $X$  is called

- (1) a preopen set [11] if  $A \subseteq intcl(A)$  and a preclosed set if  $clint(A) \subseteq A$ .
- (2) a semiopen set [8] if  $A \subseteq clint(A)$  and a semiclosed set if  $intcl(A) \subseteq A$ .
- (3) a regular open set [17] if  $A = intcl(A)$  and a regular closed set if  $A = clint(A)$ .
- (4) a  $\pi$ -open set [25] if  $A$  is a finite union of regular open sets.
- (5) regular semi open [4] if there is a regular open  $U$  such  $U \subseteq A \subseteq cl(U)$ .

**Definition: 1.2** A subset  $A$  of  $(X, \tau)$  is called

- (1) generalized closed set (briefly, g-closed) [9] if  $cl(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is open in  $X$ .
- (2) regular generalized closed set (briefly, rg-closed) [13] if  $cl(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is regular open in  $X$ .
- (3) generalized preregular closed set (briefly, gpr-closed) [6] if  $pcl(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is regular open in  $X$ .
- (4) weakly generalized closed set (briefly, wg-closed) [12] if  $clint(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is open in  $X$ .
- (5)  $\pi$ -generalized closed set (briefly,  $\pi$ g-closed) [5] if  $cl(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is  $\pi$ -open in  $X$ .

---

**\*Corresponding author: \*M. Mariasingam<sup>2</sup>, \*E-mail: [aur2002in@yahoo.com](mailto:aur2002in@yahoo.com)**

- (6) weakly closed set (briefly, w-closed)[15] if  $cl(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is semi open in  $X$ .  
 (7) regular weakly generalized closed set (briefly, rwg-closed)[12] if  $cl_{int}(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is regular open in  $X$ .  
 (8) rw-closed [1] if  $cl(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is regular semi open.  
 (9) \*g-closed [18] if  $cl(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is w-open.

The complements of the above mentioned closed sets are their respective open sets.

**Definition: 1.3** A space  $(X, \tau)$  is called  $T_{1/2}$ - space [9] if every g-closed set is closed.

## 2. #REGULAR GENERALIZED CLOSED SETS AND THEIR BASIC PROPERTIES

We introduce the following definition

**Definition: 2.1** A subset  $A$  of a space  $X$  is called #regular generalized closed (briefly #rg-closed) set if  $cl(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is rw-open. We denote the set of all #rg- closed sets in  $X$  by #RGC( $X$ ).

First we prove that the class of #regular generalized closed sets properly lies between the class of closed sets and the class of rg-closed sets.

**Theorem: 2.1** Every closed sets are #rg-closed sets, but not conversely.

**Proof:** The proof follows from the definition.

The converse of the above theorem need not be true as seen from the following example.

**Example: 2.1** Let  $X = \{a, b, c, d\}$  be with topology  $\tau = \{X, \phi, \{a\}, \{b\}, \{a, b\}, \{a, b, c\}\}$  then the set  $A = \{a, d\}$  is #rg-closed but not closed set in  $X$ .

**Corollary: 2.1** Every regular closed set is #rg - closed but not conversely.

**Proof:** Follows from Stone[17] and theorem 2.1.

**Corollary: 2.2** Every  $\delta$ -closed set is #rg - closed but not conversely.

**Proof:** Follows from Velicko[20] and theorem 2.1.

**Corollary: 2.3** Every  $\theta$ -closed set is #rg - closed but not conversely.

**Proof:** Follows from Velicko[20] and theorem 2.1.

**Corollary: 2.4** Every  $\pi$ -closed set is #rg-closed but not conversely.

**Proof:** Follows from Dontchev and Noiri [5] and theorem 2.1.

**Theorem: 2.2.** Every #rg-closed sets are rg-closed but not conversely.

**Proof:** Let  $A$  be a #rg- closed. Let  $A \subseteq U$  and  $U$  is regular open. Since  $U$  is regular open,  $U$  is rw-open. Now  $A \subseteq U$  and  $A$  is #rg- closed then  $cl(A) \subseteq U$ . Therefore  $A$  is rg - closed.

The converse of the above theorem need not be true as seen from the following example.

**Example: 2.2** Let  $X = \{a, b, c, d\}$  be with topology  $\tau = \{X, \phi, \{a\}, \{b\}, \{a, b\}, \{a, b, c\}\}$  then the set  $A = \{a, b\}$  is rg-closed but not #rg-closed set in  $X$ .

**Theorem: 2.3** Every #rg-closed sets are \*g-closed but not conversely.

**Proof:** Let  $A$  be a #rg - closed. Let  $A \subseteq U$  and  $U$  is w- open. Since  $U$  is w - open,  $U$  is rw-open. Now  $A \subseteq U$  and  $A$  is #rg- closed then  $cl(A) \subseteq U$ . Therefore  $A$  is \*g-closed.

The converse of the above theorem need not be true as seen from the following example.

**Example: 2.3** Let  $X = \{a, b, c, d\}$  be with topology  $\tau = \{X, \emptyset, \{a\}, \{b\}, \{a, b\}\}$  then the set  $A = \{c\}$  is  $*g$ -closed but not  $\#rg$ -closed set in  $X$ .

**Theorem: 2.4** Every  $\#rg$ -closed sets are  $\pi g$ -closed but not conversely.

**Proof:** Let  $A$  be a  $\#rg$ -closed. Let  $A \subseteq U$  and  $U$  is  $\pi$ -open. Since  $U$  is  $\pi$ -open,  $U$  is  $rw$ -open. Now  $A \subseteq U$  and  $A$  is  $\#rg$ -closed then  $cl(A) \subseteq U$ . Therefore  $A$  is  $\pi g$ -closed.

The converse of the above theorem need not be true as seen from the following example.

**Example: 2.4** Let  $X = \{a, b, c, d\}$  be with topology  $\tau = \{X, \emptyset, \{a\}, \{b\}, \{a, b\}, \{a, b, c\}\}$  then the set  $A = \{c\}$  is  $\pi g$ -closed but not  $\#rg$ -closed set in  $X$ .

**Theorem: 2.5** Every  $\#rg$ -closed sets are  $g$ -closed but not conversely.

**Proof:** Let  $A$  be a  $\#rg$ -closed. Let  $A \subseteq U$  and  $U$  is open. Since  $U$  is open,  $U$  is  $rw$ -open. Now  $A \subseteq U$  and  $A$  is  $\#rg$ -closed then  $cl(A) \subseteq U$ . Therefore  $A$  is  $g$ -closed.

The converse of the above theorem need not be true as seen from the following example.

**Example: 2.5** Let  $X = \{a, b, c, d\}$  be with topology  $\tau = \{X, \emptyset, \{a\}, \{b\}, \{a, b\}\}$  then the set  $A = \{d\}$  is  $g$ -closed but not  $\#rg$ -closed set in  $X$ .

**Remark: 2.1** From the above discussions we have the following implications. In the following diagram, by  $A \longrightarrow B$  means  $A$  implies  $B$  but not conversely.

Diagram- 1

**Theorem: 2.6** The union of two  $\#rg$ -closed subsets of  $X$  is also  $\#rg$ -closed subset of  $X$ .

**Proof:** Assume that  $A$  and  $B$  are  $\#rg$ -closed set in  $X$ . Let  $U$  be  $rw$ -open in  $X$  such that  $A \cup B \subseteq U$ . Then  $A \subseteq U$  and  $B \subseteq U$ . Since  $A$  and  $B$  are  $\#rg$ -closed,  $cl(A) \subseteq U$  and  $cl(B) \subseteq U$ . Hence  $cl(A \cup B) = (cl(A) \cup cl(B)) \subseteq U$ . Thus  $cl(A \cup B) \subseteq U$ .

Therefore  $A \cup B$  is  $\#rg$ -closed set in  $X$ .

**Remark: 2.2** The intersection of two  $\#rg$ -closed sets in  $X$  is generally not  $\#rg$ -closed set in  $X$ .

**Example: 2.6** Let  $X = \{a, b, c, d\}$  be with topology  $\tau = \{X, \emptyset, \{a\}, \{b\}, \{a, b\}\}$  then the set  $A = \{a, d\}$  and  $B = \{a, c\}$  are  $\#rg$ -closed but  $A \cap B = \{a\}$  is not  $\#rg$ -closed set in  $X$ .

**Theorem: 2.7** Let  $A$  be a  $\#rg$ -closed set in  $X$  then  $cl(A) \setminus A$  does not contain any non empty  $rw$ -closed set.

**Proof:** Let  $F$  be a non empty  $rw$ -closed subset of  $cl(A) \setminus A$ . Then  $A \subseteq X \setminus F$  where  $A$  is  $\#rg$ -closed and  $X \setminus F$  is  $rw$ -open. Then  $cl(A) \subseteq X$ . For equivalently  $F \subseteq X \setminus cl(A)$ . Since by assumption  $F \subseteq cl(A)$ , we get a contradiction.

The converse of the above theorem need not be true seen from the following example.

**Example: 2.7** If  $cl(A) \setminus A$  contains no nonempty rw-closed subset in  $X$ , then  $A$  need not be #rg-closed set. let

$X = \{a, b, c, d\}$  with topology  $\tau = \{X, \phi, \{a\}, \{b\}, \{a, b\}\}$ . Let  $A = \{c\}$  then  $cl(A) \setminus A = \{c, d\} \setminus \{c\} = \{d\}$  does not contain non empty rw-closed set in  $X$ , but  $A$  is not #rg-closed.

**Corollary: 2.5** If a subset  $A$  of  $X$  is an #rg-closed set in  $X$ , then  $cl(A) \setminus A$  does not contain any non empty regular closed set in  $X$ , but not conversely.

**Proof:** Follows from theorem 2.7 and the fact that every regular closed set is rw-closed.

**Corollary: 2.6** Let  $A$  be #rg – closed in  $(X, \tau)$ , Then  $A$  is closed if and only if  $cl(A) \setminus A$  is rw- closed.

**Proof: Necessity:** Let  $A$  be #rg– closed. By hypothesis  $cl(A) = A$  and so  $cl(A) \setminus A = \phi$  which is rw-closed.

**Sufficiency:** Suppose  $cl(A) \setminus A$  is rw-closed. Then by Theorem 2.7,  $cl(A) \setminus A = \phi$ . That is  $cl(A) = A$ . Hence  $A$  is closed.

**Theorem: 2.8** For every point  $x$  of a space  $X$ ,  $X \setminus \{x\}$  is #rg– closed (or) rw- open.

**Proof:** Suppose  $X \setminus \{x\}$  is not rw-open. Then  $X$  is the only rw-open set containing  $X \setminus \{x\}$ . This implies  $cl(X \setminus \{x\}) \subseteq X$ . Hence  $X \setminus \{x\}$  is #rg– closed.

**Theorem: 2.9** If  $A$  is a #rg – closed subset of  $(X, \tau)$  such that  $A \subseteq B \subseteq cl(A)$  then  $B$  is also #rg- closed subset of  $(X, \tau)$ .

**Proof:** Let  $U$  be a rw-open set in  $(X, \tau)$  such that  $B \subseteq U$ . Then  $A \subseteq U$ . Since,  $A$  is #rg – closed, then  $cl(A) \subseteq U$ . Now, since  $cl(A)$  is closed,  $cl(B) \subseteq cl(cl(A)) = cl(A) \subseteq U$ . Therefore  $B$  is also #rg – closed.

**Remark:** The converse of the above theorem need not be true in general. Consider the topological space  $(X, \tau)$  where  $X = \{a, b, c\}$  and  $\tau = \{X, \phi, \{a\}, \{b\}, \{a, b\}\}$ . Let  $A = \{b, c\}$  and  $B = \{a, b, c\}$ . Then  $A$  and  $B$  are #rg-closed sets in  $(X, \tau)$  but  $A \subseteq B$  is not a subset in  $cl(A)$ .

**Theorem: 2.10** If a subset  $A$  of a topological space  $X$  is both rw-open and #rg- closed then it is closed.

**Proof:** Suppose a subset  $A$  of a topological space  $X$  is both rw-open and #rg-closed. Now  $A \subseteq A$ . Then  $cl(A) \subseteq A$ . Thus  $A$  is closed.

**Corollary: 2.7** Let  $A$  be rw-open and #rg-closed in  $X$ . Suppose that  $F$  is closed in  $X$ . Then  $A \cap F$  is a #rg-closed set in  $X$ .

**Proof:** Let  $A$  be rw-open and #rg-closed in  $X$  and  $F$  be closed. By theorem 2.10,  $A$  is closed. So  $A \cap F$  is closed and hence  $A \cap F$  is #rg-closed set in  $X$ .

**Theorem: 2.11** If  $A$  is open and g-closed then  $A$  is #rg-closed.

**Proof:** Let  $A$  be an open and g-closed set in  $X$ . Let  $A \subseteq U$  and  $U$  be rw-open in  $X$ . Now  $A \subseteq A$ . By hypothesis  $cl(A) \subseteq A$ . That is  $cl(A) \subseteq U$ . Thus  $A$  is #rg-closed.

**Remark:**

1. If  $A$  is regular open and rg-closed then  $A$  is #rg-closed set.
2. If  $A$  is g-open open and g<sup>-</sup>-closed then  $A$  is #rg-closed set.
3. If  $A$  is  $\pi$ - open and  $\pi$ g-closed then  $A$  is #rg-closed set.
4. If  $A$  is semi open and w-closed then  $A$  is #rg-closed set.
5. If  $A$  is regular semi open and rw-closed then  $A$  is #rg-closed set.

**Theorem: 2.12** If a subset  $A$  of a topological space is both open and wg-closed then it is #rg-closed.

**Proof:** Suppose a subset  $A$  of  $X$  is both open and wg-closed. Let  $A \subseteq U$  with  $U$  is rw-open in  $X$ . Now  $cl(int(A)) \subseteq A$ . Since  $A$  is open,  $int(A) = A$ . Then  $cl(int(A)) = cl(A) \subseteq A \subseteq U$ . Hence  $A$  is #rg closed set.

**Definition: 2.2** A space  $X$  is called a  $T_{\#rg}$ -space if every  $\#rg$ -closed set in it is closed.

**Example: 2.8** Let  $X = \{a, b, c\}$  with  $\tau = \{\emptyset, X, \{a\}\}$ . Then  $\#RGC(X) = \{\emptyset, X, \{b, c\}\}$ . Thus  $(X, \tau)$  is a  $T_{\#rg}$ -space.

**Example: 2.9** Let  $X = \{a, b, c, d\}$  with  $\tau = \{\emptyset, X, \{a\}, \{b\}, \{a, b\}, \{a, b, c\}\}$ . Then  $\#RGC = \{\emptyset, X, \{d\}, \{a, d\}, \{b, d\}, \{c, d\}, \{a, b, d\}, \{b, c, d\}, \{a, c, d\}\}$ . Here the set  $\{a, d\}$  is  $\#rg$ -closed but not closed in  $X$ . Thus  $(X, \tau)$  is not a  $T_{\#rg}$ -space.

**Theorem: 2.13.** A space  $X$  is  $T_{\#rg}$ -space if and only if every singleton of  $X$  is either  $rw$ -closed or open.

**Proof: Necessity-** Let  $x \in X$  be such that  $\{x\}$  is not  $rw$ -closed. Then  $X \setminus \{x\}$  is not  $rw$ -open. So  $X$  is the only  $rw$ -open set containing  $X \setminus \{x\}$ . This implies that  $X \setminus \{x\}$  is  $\#rg$ -closed. By assumption,  $X \setminus \{x\}$  is closed. Then  $\{x\}$  is open.

**Sufficiency:** Let  $A$  be a  $\#rg$ -closed subset of  $X$  and let  $x \in cl(A)$ . By assumption, we have following cases.

- (1)  $x$  is open, but  $x \in cl(A)$ , so  $x \in A$
- (2)  $x$  is  $rw$ -closed. By theorem 2.7,  $x \notin cl(A) \setminus A$ , but  $x \in cl(A)$  so  $x \in A$ .

Hence  $cl(A) = A$ . That is  $A$  is closed.

**Theorem: 2.14** Every  $T_{1\Omega}$ -space is  $T_{\#rg}$ -space, but not conversely.

**Proof:** Let  $X$  be a  $T_{1\Omega}$ -space and  $A$  be a  $\#rg$ -closed set in  $X$ . We have, every  $\#rg$ -closed set is  $g$ -closed. Hence  $A$  is  $g$ -closed. Since it is a  $T_{1\Omega}$ -space,  $A$  is closed in  $X$ . Hence  $X$  is  $T_{\#rg}$ -space.
